ABSTRACT

Background The COVID-19 pandemic has already stressed the healthcare system in the world. Many hospitals have been overwhelmed by the large number of patients with COVID-19. Due to the shortage of equipment and personnel and the highly contagious nature of COVID-19, many other healthcare services are on hold. However, at Beijing Tiantan Hospital, a rapid response system has been in place so that routine care is not interrupted. We, therefore, would like to share our hospital-wide prevention and management policy during this pandemic to help other healthcare systems to function in this crisis.

Method Tiantan hospital is one of the leading neuroscience institutions in the world. With 1650 beds, its annual inpatient admission exceeds 30 000 patients. Its COVID-19 rapid response policy was reviewed for its functionality.

Results There are nine key components of this policy: an incident management system; a comprehensive infection prevention and control, outpatient triage and flow system; a designated fever clinic; patient screening and administration; optimised surgical operations, enhanced nucleic acid testing; screening of returning employees; and a supervision and feedback system. In addition, a specific protocol was designed for treating patients with acute stroke.

Conclusion A comprehensive policy is helpful to protect the employee from infection and to provide quality and uninterrupted care to all who need these, including patients with acute ischaemic stroke.

Beijing Tiantan Hospital, Capital Medical University, is known for its outstanding medical care and groundbreaking research in neurology and neurosurgery. With 3210 full-time employees and 1650 inpatient beds, Beijing Tiantan Hospital is both a research hospital and a teaching hospital. Patient visits at Beijing Tiantan Hospital steadily increases over 1 000 000 outpatient visits and 30 000 inpatient admissions per year.

The COVID-19 pandemic has already stressed the healthcare systems throughout the world. Rapid response to the outbreak of COVID-19 with timely prevention and management was implemented quickly at Beijing Tiantan Hospital. Healthcare services

have not been interrupted for those who are critically ill, needing complex major surgeries, with high-risk pregnancy, tumours, stroke and haemodialysis. Here, we would like to share our experience on the policies implemented during this uncertain time.

INCIDENT MANAGEMENT SYSTEM

The Prevention and Control Leadership Group, chaired by the president of the hospital, was formed in Beijing Tiantan Hospital as the commanding centre for daily operations of COVID-19 prevention and management. A multidisciplinary planning committee was formed to facilitate the cooperation across all divisions, including the administration office, medical service office, office for disease control and prevention, infection management, nursing administration, outpatient clinic, pharmacy, hospital security, pharmaceutical equipment and materials management, bioengineering, general affairs, planning and construction division, and information and communications technology (figure 1). The 'Action Plan for Prevention and Control of COVID-19' was then developed. Daily meetings were scheduled for updates according to the local and national health guidance.

An ad hoc incident management group was formed. It included representatives from senior consultants, infection prevention and control, quality control and medical personnel. Medical consultation, education and training, and communication were conducted via either regular meetings or video teleconferences.

COMPREHENSIVE INFECTION PREVENTION AND CONTROL

Over 50 official policies have been released and updated by the prevention and control office on COVID-19 prevention and control for the emergency room and outpatient clinic, fever clinic, inpatient department, and

departments of surgery, supply, engineering and maintenance, environmental (housekeeping) services and human resources. Emergency preparedness plans were developed for the laboratory diagnosis centre, endoscope centre, operating rooms, ultrasound department, radiology department, pulmonary function examination and ECG rooms. A designated location, separated from other clinical areas, has been established for the admission of patients with possible COVID-19. A standard operating

procedure and sterilisation process have been developed in all other departments.

OUTPATIENT MANAGEMENT POLICY

Clinical booking for doctor's appointment ensured the social distancing. All patients are required to make an appointment in the clinic, and for those urgent and life-threatening cases, patients are advised to go to the emergency room. On checking in, a patient would have their body temperature checked, and questionnaires on any possible COVID-19 exposure and recent travelling history are filled out before going into a room. The respiratory clinic is now separated from other clinics. An isolation area has been set up in every clinic for patients with suspected COVID-19. All febrile patients will be sent to the fever clinic for further evaluation and therapy.

FEVER CLINIC AS A VITAL PASS

The fever clinic is located in the infection prevention and control building, which is separate from all other clinics. It is in charge of the screening, diagnosis and treatment of all febrile patients. Nucleic acid testing is used to confirm the diagnosis of COVID-19 when suspected based on physical signs and symptoms. The confirmed cases are then transferred to the COVID-19 designated hospitals. The patients who had been released from quarantine were required to undergo self-isolation and were followed up for further evaluation.

PATIENT SCREENING AND ADMINISTRATION

Emergency visits and admissions of patients for other medical conditions have decreased due to the epidemic. We designated a number of 340 reserved beds for COVID-19. Some units or services were combined in order to minimise the stuffing needs and to improve the

operation efficiency. Each department designated three inpatient rooms for care of suspected COVID-19 cases that need ventilator support: one room for quarantine, next for buffering and the third one for sanitising.

A screening clinic has been set up since the outbreak of COVID-19 (figure 2). All patients admitted to the hospital from the outpatient clinic must be screened by a physician. These patients will have to fill out the questionnaires and have their body temperature taken, and undergo blood tests and a chest CT scan. The surgical patients must undergo further anaesthesia assessment before being admitted to the hospital. Nucleic acid testing for COVID-19 must be performed on all patients. Only patients who tested negative twice could be admitted.

All patients who come to the emergency room must be screened with a chest CT scan and a throat swab culture. According to their illness, they will be admitted to the transitional care unit (TCU) of the corresponding department if suspected of COVID-19 in order to reduce the risk of infection. These TCUs have been set up in the departments of neurosurgery, neurology, surgery, and internal medicine since 25 February 2020. Only patients who test negative twice in the TCUs could be admitted to the general ward rooms (figure 3).

OPTIMISE ENDOVASCULAR TREATMENT FOR ACUTE STROKE AND SURGICAL OPERATIONS TO ENSURE SAFETY

The management of the operating rooms and the interventional and surgical procedures have been adjusted to ensure endovascular treatment and surgical safety (figures 4 and 5). Outpatient operations are performed

only after COVID-19 screening was negative. All operations on patients with suspected COVID-19 must be done in a negative pressure operating room with strictly controlled air flow. A protocol has been in place to facilitate the transport of suspected cases within the facility.

ENHANCE NUCLEIC ACID TESTING

Beijing Tiantan Hospital is one of the few hospitals in Beijing that could apply nucleic acid testing for COVID-19 during the initial phase of the epidemic. By performing nucleic acid testings to all febrile patients and admitted patients, the risk of nosocomial infection has been significantly reduced, which facilitates the normal operation of the hospital.

SCREENING OF RETURNING EMPLOYEES

All staff, including contractors, volunteers and medical students, returning back to Beijing must also be screened by a physician at the screening clinic, including completing the epidemiological questionnaires, having their body temperatures taken, and undergoing blood tests and a chest X-ray. Only the staff who were tested and confirmed to be uninfected could get back to work.

SUPERVISION AND IMPROVEMENT

Given the decreased patient visits and admissions in some clinics, a number of medical staff from these clinics were trained for the job of prevention and control of nosocomial infections. An inspection team has been organised to ensure compliance with policies and procedures in

each clinic and department and to provide feedback to those that need improvement.

A timely, hospital-based response to manage the outbreak of COVID-19 plays a critical role within the health system in order to maintain services to the community. These preparation measures outlined in Beijing Tiantan Hospital might be helpful to other healthcare institutions that need similar policies in their fight against COVID-19.
